Amendments To The Claims:

Please amend the claims as indicated below.

Listing of Claims:

- (Currently amended) A system for controlling fuel vapor recirculation during refueling of a tank from a dispensing nozzle, during refueling of a tank from a dispensing nozzle the system comprising:
 - (a) a filler tube with a means for sealing about the nozzle;
 - a means defining a vapor recirculation path from the tank to the filler tube at a location downstream of said means for sealing about the nozzle;
 - (c) a vapor storage device disposed externally of the tank and connected to receive fuel vapor from the tank; and,
 - (d) a flow control valve disposed in said recirculating recirculation path, said flow control valve responsive to a predetermined pressure differential across the valve to change from a first relatively low flow rate to a second substantially higher flow rate.
- 2. (Original) The system defined in claim 1, wherein said flow control valve includes a valve obturator moveable between an open and closed position with a passage therethrough providing said first flow rate when said obturator is in said closed position, said obturator providing said second flow rate in said open position.
- 3. (Original) The system defined in claim 1, wherein said flow control valve includes a piston having a passage therethrough.
- 4. (Currently Amended) The system defined in claim 1, wherein said recirculation path includes a float operated valve is disposed fluidically in series with said flow control valve[[;]].

- 5. (Original) The system defined in claim 4, wherein said flow control valve and said float operated valve are mounted in a common housing through an access opening in the tank.
- (Original) The system defined in claim 5, wherein said flow control valve and said float operated valve are mounted in vertically aligned arrangement.
- 7. (Currently Amended) The system defined in claim 1, wherein said flow control valve wherein said flow control valve is operative to change to said second flow rate at a pressure differential thereacross of about 1 kPa (4 in. H₂O).
- (Currently Amended) A method of controlling fuel vapor recirculation during refueling of a tank from a dispensing nozzle comprising:
 - (a) providing a tank filler tube with a nozzle receiving cup end disposing an annular seal in the cup and sealing bout about the nozzle upon insertion therein;
 - (b) providing a vapor recirculation passage from the tank to the filler tube cup downstream of the nozzle seal;
 - (c) disposing a pressure responsive flow control valve in said recirculation passage and changing the rate of flow in said passage from a first rate to a second significantly higher rate when said valve experiences a predetermined pressure differential thereacross.
- 9. (Original) The method defined in claim 8, wherein said step of disposing a flow control valve includes disposing a valve with an obturator having a passage therethrough; and, said step of changing the rate includes moving the obturator between an open and closed position.
- 10. (Onginal) The method defined in claim 8, further comprising disposing a float operated valve in said recirculation line.

02-ASD-333 (SR)

- 11. (Original) The method defined in claim 10, wherein said step of disposing a float operated valve includes disposing said flow control valve and said float operated valve in a common housing.
- 12. (Original) The method defined in claim 11, wherein said step of disposing in a common housing includes mounting said housing through an access opening in the tank.
- 13. (Original) The method defined in claim 8, wherein said step of disposing a flow control valve includes disposing a valve with a moveable piston and forming a passage through the piston for providing the first flow rate.
- 14. (Original) The method defined in claim 8, further comprising disposing a float operated valve vertically aligned with said flow control valve.
